Fact sheet

European spruce bark beetle

Description
Adults of the European spruce bark beetle (*Ips typographus*) are small (4.0–5.5 mm) cylindrical beetles, dark brown to black in colour. The eggs, larvae and pupae are very similar in appearance to other species of *Ips*.

Male beetles bore into the inner bark and construct a nuptial chamber and emit pheromones that attract from one to four females. Each female then bores an egg gallery out from the nuptial chamber and lays approximately 50 eggs. After the eggs hatch, the larvae feed in galleries which radiate at right angles to the egg gallery. The newly emerged adults feed for a short time under the bark before emerging through small (2–3 mm) round exit holes. The young adults may swarm en-mass to locate new hosts. Alternatively, under cold conditions, they will overwinter in litter or under the bark.

Primary hosts
The European spruce bark beetle is one of the most damaging insect pests of Spruce (*Picea*) in Europe and Asia. It normally infests diseased, damaged or recently fallen trees, including windthrow, harvest slash or logs. With high population levels in an outbreak, it can colonise and kill apparently healthy trees, including species of Pine (*Pinus*), Fir (*Abies*) and Larch (*Larix*).

In Europe, outbreaks can be caused by disturbances such as fire or in areas presenting large volumes of harvesting residue. Stands that have been stressed by extreme weather conditions, including periods of drought, are also susceptible.

Symptoms
As with most bark beetles, it transmits Blue stain fungi (e.g. *Ceratocystis* and *Ophiostoma* spp.) which interfere with water translocation and prevent water transport to the foliage. Blue stain fungi also invade the sapwood, affecting the value and aesthetic qualities of milled timber.

Under low population levels, the crowns can appear a lighter green colour, and green needles can often be seen on the ground. In a mass attack the needles can turn reddish-brown in colour as a result of desiccation caused by the rapid spread of Blue stain fungi.
Other symptoms of bark beetle attack include the presence of red-brown borer dust in bark crevices or at the base of the trunk and small pitch (resin) tubes extruding from the bark.

**What it can be confused with**

The *Ips* genus has more than 30 species and distinguishing between them can be difficult. The number and shape of the spines on their elytral declivity (the steeply sloped section at the back of their wing covers) is an important feature to distinguish between species of *Ips*. The third spine on each side of the elytral declivity of European spruce bark beetles is the largest one, and is club like on the tip. The Five-spined bark beetle (*Ips grandicollis*), which is established in Australia, has five of these spines.

**Plant part affected**

European spruce bark beetles prefer mature trees and usually infest the lower and middle parts of the trunk.

**Time of year pest is most likely to be seen**

In Europe, depending on the temperature, young adults normally emerge in spring and are capable of flying tens of kilometres to locate suitable host material.
